

Characterization and nutritional assessment of traditional dairy products from the Zlatibor region, Republic of Serbia

D. Milićević*, G. Krešić, D. Vranić, T. Lešić, J. Nedeljković-Trailović, S. Janković and J. Pleadin

Abstract

The aim of this study was to determine the nutritional properties of raw milk, cheese and a traditional creamy dairy product called *kajmak* originating from the Zlatibor region in Serbia. Chemical composition, minerals, fatty acid (FA) profile, lipid quality indices, and the dietary intake of saturated fatty acids (SFA), cholesterol, salt and sodium were investigated in three sampling sessions during the period June–September 2019. All chemical properties of raw milk, cheese and *kajmak* differed significantly ($P < 0.05$), except lactose, salt and total proteins. Palmitic acid (C16:0) was present in the highest share, followed by oleic (C18:1 cis-9) and myristic (C14:0) acids, with no significant differences ($P > 0.05$) between

products. Among the FAs, conjugated linoleic acids (CLA) were determined, and mean values of total FAs ranged from 0.16% in raw milk and *kajmak* to 0.31% in cheese. The recommended values for the lipid quality indices were not obtained for the analysed products. Despite a high sodium content, the tested dairy products can be considered valuable sources of calcium, chromium, zinc and selenium. In the future, additional efforts should be employed in product modification with the aim of optimising nutritional value and to obtain the protect designation of origin.

Key words: raw milk; cheese and *kajmak*; nutritional assessment; traditional recipes, Zlatibor region

Introduction

Due to their nutritional value and the health-related benefits of regular consumption, milk and dairy products are

an integral part of the daily diet during the entire human lifespan (US Department of Health and Human Services, 2020). These

Dragan MILIĆEVIĆ*, DVM, PhD, Principal Research Fellow (Corresponding author, e-mail: dragan.milicevic@inmes.rs), Danijela VRANIĆ, PhD, Senior Research Associate, Saša JANKOVIĆ, PhD, Senior Research Associate, Belgrade, Serbia; Greta KREŠIĆ, BSc, PhD, Full Professor, Faculty of Tourism and Hospitality Management, University of Rijeka, Opatija, Croatia; Tina LEŠIĆ, MSc, BSc, Expert Associate, PhD student, Jelka PLEADIN, BSc, PhD, Scientific Advisor in Tenure, Full Professor, Croatian Veterinary Institute, Zagreb, Croatia; Jelena NEDELJKOVIĆ-TRAILOVIĆ, DVM, PhD, Full Professor, Faculty of Veterinary Medicine, University of Belgrade, Belgrade, Serbia

products are rich in necessary building and regulating components, including minerals, fat-soluble vitamins (A, D, E, and K), and fat as a source of energy (Vulić et al., 2021). The protein in cow milk is of high-quality, containing a good balance of all the essential amino acids, including lysine (defined as protein that supports maximal growth). Cow milk accounts for 83 percent of the global overall milk production (FAOSTAT, 2012). Over the past decade, the concept of dairy production has changed dramatically, with increasing orientation towards the production of “value-added products”, some of which are segmented into the “health and wellness” market. Studies have also shown that milk from traditional family farms, especially in Mediterranean countries, represent a valuable raw material for the production of different dairy products, such as high quality hard cheese as the most important product (Alichanidis and Polychroniadou, 2008).

The Zlatibor region in Serbia is a hilly and mountainous area with widespread traditional, artisanal processing of dairy products. However, recently, the focus in dairy manufacturing conditions has shifted towards improving the quality and safety of dairy products. Due to its specific geographical position and natural features, the Zlatibor region is one of the most interesting highlands area in Southeast Europe and one of the top two tourism destinations in Serbia. The strong interest of tourists in traditional, local products gives the potential for additional valorisation of Zlatibor dairy products, with the need to increase their visibility, particularly with protection of the label of geographical indices. Furthermore, the quality of milk and dairy products tends to be tailored to meet the demand of the national culture, economy, and public health, and to promote their further development.

To date, there have been no studies conducted to characterise the nutritional

composition of milk and dairy products from this area, with a detailed profile of their mineral and FA contents, and this information is also not provided on any labels, which consumers view when making purchasing decisions. Therefore, the aim of this study was to provide characterization and a nutritional assessment of raw milk, cheese and *kajmak* produced in this region according to traditional recipes, and to determine the relationships with the corresponding milk. Measuring the main chemical parameters of these products also creates a foundation for the development of novel products and to improve the quality of existing products.

Materials and methods

Production technology

The dairy cows giving the milk analysed in this study, all of the Simmental breed, were fed silage originating from a defined locality, with a minor extent of concentrated food originating from or outside the defined area of production. The local small dairy has a capacity of 1,500 litres of milk per day and processes milk only from registered agricultural farms (30), situated in the southwestern mountain region of Zlatibor, Serbia (43°31' - 43°51' N, 19°28' - 19°56' E, with a mean elevation of about 1000 m).

The technological process of cheese and *kajmak* production is based on traditional methods, adapted to the conditions of production in dairies. After receiving the milk, it is pasteurized and poured into creamers. After removing the cream, cheese is made from the remaining milk. Milk coagulation is initiated by the action of rennet. From the received 1500 L of milk, on average, 170 kg of cheese and about 40 kg of *kajmak* are obtained. The finished products are packed in plastic packaging, namely cheese in packages of 1 kg and 5 kg, and *kajmak* in packages of 300 g, 500 g and 1000 g. Entities that

are involved in the production and trade of these products must be entered in the Register of animal breeding holdings and the Central Register of holdings that is kept by the Serbian Ministry of Agriculture.

Sampling procedures and analysis

For the analysis of raw milk material, a pooled sample of cow's milk was used, collected from individual breeders (small farms), whereas samples of cheese and *kajmak* were produced by a small, local dairy. In order to assess homogeneity, all samples (raw milk, cheese and *kajmak*) were taken three times during the period June–September 2019 in the same time intervals, every 40 days, from the same producer and in five replicates, where each sample had a weight of at least 300 g (SFRY Official Gazette 32/83). After sampling, all samples were kept at 4°C and analysed within 24 hours of receipt at the laboratory. All chemical analysis were performed in duplicate using accredited or validated analytical methods, with applied quality control (certified reference materials) and regularly annual participation in proficiency test schemes.

Chemical properties

Methods for determination of the basic chemical ingredients in raw milk (moisture, dry matter, milk fat and total proteins) were carried out completely in accordance with the Ordinance on sampling methods and methods of chemical and physical analysis of milk and milk products (SFRY Official Gazette 32/83). Moisture content in cheese and *kajmak* was determined by drying of 2–3 g of sample at 105°C until a constant weight was obtained (FIL-IDF, 1987), while dry matter (DM) was calculated as 100-% of moisture. pH value was measured with a pH meter CYBER SCAN pH 510 (Eutech, Netherlands). Cheese and *kajmak* fat content were determined using the Gerber method (FIL-IDF, 1981). Fat in

dry matter (Fat/DM %) was calculated by the formula $\text{Fat/DM \%} = (\text{cheese fat \%} \times 100) / \text{cheese DM \%}$. For determination of salt content, after acidification, silver nitrate solution was added to the sample, and further titrated with a standard volumetric ammonium thiocyanate solution (AOAC, 1984). To determine total protein, 1 g of sample was weight and after addition of catalyst (2 tablets) and concentrated sulphuric acid (12 mL), its content was determined by the Kjeldahl method (FIL-IDF, 2002), with use of Kjeltac Auto 1030 Analyzer (Foss Tecator AB, Hoganas, Sweden).

Determination of cholesterol was performed according to Maraschiello et al. (1996), using high performance liquid chromatography on an HPLC Waters - 2695 Separation module, with a Photo diode array detector (PDA detector) Waters 2995 (Milford, MA, USA). Chromatographic separation was achieved on a Phenomenex Luna C 18 (2) column (150 mm x 3.0 mm, particle size 5 µm), with the appropriate pre-column, isocratic, with mobile phase isopropanol-acetonitrile, 20%: 80%, v/v, and injected volume of 10 µL. Cholesterol was determined by absorption at a wavelength of 210 nm.

Sugars were determined by liquid chromatography with detection by measurement of the refractive index (HPLC-RI). The chromatographic system consisted of an isocratic HPLC pump 1515 (Waters, Milford, MA, USA), an autosampler 717 plus (Waters, Milford, MA, USA), detector (2414 Refractive Index Detector) and column temperature control system (Temperature control module). The amino column Luna NH2 150x4.6 mm, Phenomenex, Torrance (CA, USA) was used for the chromatographic separation of sugars. The mobile phase is a mixture of water: acetonitrile 20:80 v/v, with flow of 2 mL/min. The temperature of the detector and the column was 30°C. The injected sample volume was

10 μL and analysis duration was 10 min. For sample preparation, 20 g of sample was combined with about 50 mL boiling water, homogenized for 1 min at Ultraturrax at about 10,000 rpm, and then cooled. To this, 2 mL Carrez solution I and II were added, made up to 100 mL with water and filtered through a nylon filter with a pore size of 0.45 μm in the autosampler vial.

Mineral content

Approximately 0.5 g of the sample was transferred into a teflon vessel with 5 mL nitric acid (67% Trace Metal Grade, Fisher Scientific, Bishop, UK) and 1.5 mL hydrogen peroxide (30% analytical grade, Sigma-Aldrich, St. Louis, MA, USA) for microwave digestion. The microwave (Start D, Milestone, Sorisole, Italy) programme consisted of three steps: 5 min from room temperature to 180°C, 10 min hold at 180°C, 20 min vent. After cooling, the digested sample solutions were quantitatively transferred into disposable flasks and diluted to 100 mL with deionized water produced by a water purification system (Purelab DV35, ELGA, Buckinghamshire, UK).

Analysis of the following elements: Fe, Zn, Cu, Mn, Se, Cr, Co, Na, K, Mg and Ca, was performed by inductively coupled plasma mass spectrometry (ICP-MS), (iCap Q mass spectrometer, Thermo Scientific, Bremen, Germany). The most abundant isotopes were used for quantification. Basic operating conditions of the instrument were: RF power (1550 W); cooling gas flow (14 L/min); nebulizer flow (1 L/min); collision gas flow (1 mL/min); operating mode (Kinetic Energy Discrimination-KED); dwell time (10 ms). Standard stock solutions containing 1000 mg/L of each element (Fe, Zn, Cu, Mn, Se, Cr, Co, Na, K, Mg, Ca) were purchased from Reagecon (Shannon, Co. Clare, Ireland). These solutions were used to prepare standards for the five-point calibration curves (including zero).

Multielement internal standard (^6Li , ^{45}Sc , ^{71}Ga , ^{89}Y , ^{209}Bi) was introduced online by an additional line through the peristaltic pump, and covered a wide mass range. All solutions (standards, internal standards and samples) were prepared in 2% nitric acid.

The quality of the analytical process was verified by analysis of the certified reference materials ERM-CE278k and ERM-BB384 (Institute for Reference Materials and Measurements, Geel, Belgium). Measured concentrations were corrected for response factors of internal standards using the interpolation method and were within the range of the certified values for all isotopes.

Fatty acid profile and triglycerides

Extraction of total lipids for FA determination was performed by accelerated solvent extraction (ASE 200, Dionex, Sunnyvale, CA) with a mixture of petroleum ether and isopropanol (60:40, v/v). Preparation of fatty acid methyl esters (FAMES) was done by 0.25 M TMSH (trimethyl sulfonium hydroxide) in methanol (EN ISO 5509:2000) and their determination by capillary gas chromatography with a flame ionization detector on GC Shimadzu 2010 (Kyoto, Japan), equipped with flame ionization detector and capillary HP-88 column (100 m x 0.25 mm x 0.20 μm , J&W Scientific, USA). Separation and detection were performed under the following temperature programme: initial temperature 50°C, rate 13°C/min to 215°C, hold 10 min, rate 2°C/min to 230°C and hold 10 min. Total analysis time was 63.12 min. The injector and detector temperatures were 250°C and 280°C, respectively; split ratio 1:50; volume 1 μL , carrier gas, N_2 , 1.87 mL/min; make-up gas, N_2 , 30 mL/min; detector gases, H_2 , 40 mL/min; and synthetic air, 400 mL/min.

Triglycerides (TAG) were determined by the same equipment of the liquid chromatographer with detection

by measurement of refractive index (HPLC-RI), as described earlier for the determination of sugars. Two reverse-phase columns Luna C18 150x4.6 mm were connected in series, Phenomenex, Torrance (CA, USA) and used for chromatographic separation of TAG. The mobile phase was a mixture of acetone: acetonitrile 64:36 v/v. The flow of the mobile phase was 1 mL/min, the internal temperature of the detector 30°C, and column temperature 25°C. The injected sample volume was 10 µL and the duration of the analysis 40 min. The extraction part of the sample preparation was the same as for determination of FAs. A portion of the extracted fat was dissolved in acetone and filtered in an autosampler vial through a 0.22 µm nylon filter. The composition of TAG was determined based on their grouping by equivalent carbon number (ECN). During chromatography, the TAG elutes in the order of their ECN, i.e., the TAG with the lowest ECN have the shortest retention times (RT).

Lipid quality indices

Data on FA composition were used for the calculation of lipid quality indices, including the atherogenic index (AI), thrombogenic index (TI) and hypocholesterolaemic/hypercholesterolaemic ratio (H/H). These parameters were calculated as follows: $AI = [(C12:0 + (4 \times C14:0) + C16:0)] / [\sum MUFA + PUFA\ n-6 + PUFA\ n-3]$; $TI = (C14:0 + C16:0 + C18:0) / [0.5 \times \sum MUFA + 0.5 \times PUFA\ n-6 + 3 \times PUFA\ n-3] + (PUFA\ n-3/PUFA\ n-6)$, and $HH = (C18:1n-9 + C18:2n-6 + C20:4n-6 + C18:3n-3 + C20:5n-3 + C22:5n-3 + C22:6n-3) / (C14:0 + C16:0)$ (Ulbricht and Southgate, 1991).

Estimation of dietary intake

Dietary intake of saturated fatty acids, cholesterol, salt and minerals were estimated by calculation on the basis of consumption of 100 g of cheese and

kajmak and on the basis of the average *per capita* consumption data as published in the Household Budget Survey (Statistical Office of Republic of Serbia, 2020). The obtained values were compared with the recommendations (EC, 2011; Institute of Medicine, 2011; WHO, 2012).

Statistical analysis

All data analysis was performed using the SPSS Statistics Software package 22.0 (SPSS Statistics, IBM NY, USA, 2013). The obtained results were expressed as the mean \pm standard deviation ($\bar{X} \pm SD$), minimum (min) and maximum (max) values. To determine the statistical significance of the differences in chemical parameters and FAs composition between milk and dairy products, the one-way ANOVA test was performed. Pearson's bivariate correlation analysis was performed to determine the relationship between chemical components of milk, cheese and *kajmak*. Decisions on statistical relevance were made at the significance level of $P \leq 0.05$.

Results and Discussion

Chemical composition and mineral content

The basic chemical properties of raw milk, and the mineral content in cheese and *kajmak* originating from the Zlatibor area are shown in Tables 1, 2 and 3, respectively. The mean value of DM content of cow milk (without fat) was about 8.60%, while fat was about 4.03% and protein about 3.11% (Table 1). In the current study, the estimated mean value of the main chemical composition of raw cow milk is in accordance with the values listed in the FAO database (FAO, 2013). Therefore, raw milk produced in the Zlatibor region is whole milk and a high-quality raw material for dairy production. Milk yield and chemical composition depends on various factors, including animal breed, diet, stage of lactation,

health status and environmental factors (FAO, 2013; Vulić et al., 2021). Several studies have examined methods to improve nutrient value and sensory quality by changing the animal's diet. Also, most modern dairies begin their manufacturing process by standardizing raw milk to a specified solids content, pasteurizing it and then using for the production of dairy products.

The results of the chemical analysis of cheese and *kajmak* are summarized in Table 2. Based on the milk fat content in DM (38.44%) and moisture content (57.72%), the cheese analysed in this study was classified as a semi-fat soft cheese, while *kajmak* is intended to be consumed immediately after production, as fresh *kajmak*. Results of the chemical properties of cheese and *kajmak* obtained in this study (Table 2) are comparable with other studies (Pudja et al., 2008; Kučević et al., 2016; Miloradovic et al., 2018). The greatest variability was observed for DM (38.51-44.80%), milk fat (14.75-17.25%) and cholesterol (38.99-65.92%) content in cheese, while the chemical properties of *kajmak* was similar across the sampling period. Variations in cheese composition observed here could be explained mainly due to technological processes involved in cheese manufacturing. The nutritional profile of cheese varies with the type of milk, the type of starter culture, the method of manufacture and ripening conditions (Lešić et al., 2016). In general, the highest quantity of salt (3.51%) was

found in cheese, and was up to twice as high as in *kajmak*. This may be because the cheese was salted with NaCl, to maintain a salty taste and to ensure microbial stability by maintaining water activity (a_w) of the soft cheese. However, a high amount of salt causes the loss of minerals due to osmosis. Also, reducing the sodium content of cheese could have significant health benefits, since dairy products have been listed as the fourth largest source of dietary sodium (Grummer et al., 2012). The pH value near 5 as obtained here is key point of an optimum cheese-making process, since acidity contributes to the sensory properties of cheese, prevents bacterial growth and consequently enzyme activity and also has an effect on the distribution of minerals. The lactose content showed significant variation during the study period, with levels of 2.06 and 2.86% in cheese and *kajmak*, respectively. The average lactose content is in accordance to the type of fresh cheese and *kajmak* (1.81% and 2.11%, respectively), due to relatively short ripening period. Nevertheless, a high level of lactose in dairy products is not suitable for lactose intolerant individuals. Hence, the importance of the starter culture in cheesemaking should be pointed out, as it is necessary for sugar fermentation by lactic bacteria within in the first 10–12 h. Significant differences ($P < 0.05$) were determined between these three product types for all chemical properties (Tables 1 and 2), except the content of lactose and

Table 1. Basic chemical properties of raw milk from Zlatibor region

Parameter [%]	$\bar{X} \pm SD$	Min-Max

salt, and of total protein content between raw milk and *kajmak*. Milk fat in raw milk and cheese were strongly positively correlated ($r=0.999$, $P=0.05$), while for no significant correlation was observed between raw milk and milk products for other parameters.

The mean mineral content (Na, Ca, K, Mg, Zn, Fe, Cu, Mn, Se and Cr) in cheese and *kajmak* is shown in Table 3. Cheese contains significant amounts of calcium, zinc, selenium and chromium (4722 mg/kg, 27.1 mg/kg, 0.14 mg/kg and 0.09 mg/kg, respectively). Zlatibor cheese and *kajmak* did not differ significantly in their mineral compositions, except zinc which was significantly ($p=0.026$) higher in cheese. All minerals considered to be essential to the human diet are present in milk, so milk and dairy products are considered a good source of minerals, except iron. Milk is not a source of iron, and the high calcium and casein contents in milk inhibits the absorption of dietary non-heme iron (FAO, 2013). It is known that the mineral content in raw

cow milk varies according to different factors, such as lactation period, health status, dietary composition of animal feed, and environmental and genetic factors (Vahčić et al., 2010). Also, the technology of production has a significant effect on content and ratio of mineral compounds in dairy products (Khattab et al., 2019). Mineral composition in milk products is also related to differences in acidification, heating and salting levels. As a result of milk fermentation, the decrease in milk pH renders progressively soluble colloidal calcium phosphate, calcium bound to phosphoserines and carboxyls, as well as magnesium bound to casein (Gaucheron, 2011). The rate of acid production and the pH of whey at draining during cheesemaking are also critical factors that determine the mineral content of cheese (Raynal-Ljutovac et al., 2008). This could partly explain the wide variability of the mineral contents observed in this study, especially for Na, Ca, K and Mg.

Table 3. Mineral content of *Zlatibor cheese* and *Zlatibor kajmak*

Minerals (mg/kg)	Cheese		Kajmak	
	$\bar{X} \pm SD$	Min-max	$\bar{X} \pm SD$	Min-max

Contamination of dairy products with contaminants or residues are a still notable concern, since their presence has been related to environmental pollution (air, water, soil), substances used in animal husbandry practices, animal feedstuff production processes, and sanitary conditions. In the current study (*data not presented*), the concentrations of toxic elements (arsenic, mercury, lead, cadmium, nickel, cobalt) were far below the permissible limit. Thus, dairy products originating from Zlatibor represent a low risk to human health, in relation to dietary intake of toxic elements.

Generally, the highest content of macroelements sodium and calcium in cheese and *kajmak* can be explained due to the addition of their salts during production, while the presence of microelements can be linked to the high content of biogenic microelements (Fe, Co, Mn, Se) in the soil and consequently increased concentrations in grasses used in animal nutrition. Due to a lack of similar research in Zlatibor, we are not able to compare the results obtained

here. However, the composition and quantitative sequence of the analysed minerals in this study can be compared with earlier published data for other regional types of cheeses (Zlatar, Homolje, Sjenica) (Barać et al., 2018). The data obtained in this study suggest differences in the chemical composition and mineral content of dairy products from Zlatibor, compared to previous research in other regions.

Fatty acids, triglycerides and lipid quality indices

One of the main factors affecting cheese quality is the FA profile. The results of the FA profiles of raw milk, cheese and *kajmak* produced in the Zlatibor area are shown in Table 4. The results of the FA profiles in this study are in agreement with previous reports that confirm that more than 60 percent of the FAs in all three products are SFAs, among which the content of palmitic (C16:0) acid is highest (27.43-30.93%), followed by oleic (C18:1cis-9) (24.90-29.78%) and myristic (C14:0) (9.86-12.42%) acid content (Yao et al., 2016). However, among the FAs,

SFA – saturated fatty acids; MUFA – monounsaturated fatty acids; PUFA – polyunsaturated fatty acids

Results are expressed as mean value ± SD of five samples taken in three sampling sessions; each sample was analysed in duplicate

conjugated linoleic acids (CLA) were also determined, with mean values of total FAs in the range from 0.16% in raw milk and *kajmak* to 0.31% in cheese. The high values of CLA in milk may be linked to grazing feeding effects. Among FAs, CLA is widely studied in ruminants due its anticarcinogenic effects in experimental animals (Govari et al., 2020). The level of CLA was shown to be higher in cow and sheep milk than in other milks (Pietrzak-

Fiećko and Kamelska-Sadowska, 2020). Studies also pointed out that dairy products are the main source of CLA in the human diet and that dairy products contain on average 0.4-1.7% CLA of total FAs (Ferlay and Chilliard, 2020). In this study, no significant differences were found between raw milk, cheese and *kajmak* in the proportion of FAs, except for C4:0 between *kajmak* and milk, indicating that the FA profiles of these products

were directly related to the parent milk.

Milk fatty acids are derived almost equally from two sources: feed and *de novo* synthesised as a result of microbial activity in the rumen of the cow. *De novo* synthesised FAs (~40%) include short chain (C4:0-C12:0) and medium chain (C14:0 and partly C16:0), while other saturated fatty acids and long chain unsaturated FAs originate from feed. Therefore, the FA composition of milk may be influenced by several factors, such as diet, stage of lactation, health, and animal breed (Woods and Fearon, 2009), resulting in high variability of their FA profiles. Of all the factors that affect the amount and composition of milk fat, nutrition is the most important. Feeding systems based on herbage (Hurtaud et al., 2014), especially highland pasture (Bergamaschi et al., 2016), have been shown to yield milk and dairy products with FA profiles more beneficial to human health. Therefore, a balanced diet is a basic prerequisite for good production. However, studies have also shown that milk contains significant amounts of lauric acid (C12:0), myristic acid (C14:0), and palmitic acid (C16:0), which have been linked to negative effects on human health, especially because of increased risk of cardiovascular disease. So many studies recommend a decrease in C16:0 as this FA is present in milk fat in high concentrations (Huth and Park, 2012; FAO, 2013).

The results of triglycerides (TAG), TFA and lipid quality indices obtained in raw milk, cheese and *kajmak* samples in this study are shown in Table 4. The TAG structure of milk is responsible for the rheological properties of milk fat and its behaviour during melting and crystallization. Their composition is of interest, because it can be used to verify the origin of milk fat (Park et al., 2007). In this study, TAG composition did not differ significantly between milk and milk products and has the highest

content of CN 42-50 and lowest of CN 32-34. A similar distribution of TAG CN proportion was reported by Precht (1992) for cow milk with 8.9% for CN 32-34, 33.2% for CN 36-40 and 41.1% for CN 42-50, respectively. Dairy products typically contain 3-6% *trans* fatty acids (TFAs) per gram of fat (EFSA, 2010). However, these values depend on the diet of the animals, and neither thermal nor mechanical treatments applied during processing had any effect on the *trans*-FA content. Elaidic acid (*trans*-9 C18:1) is one of the major TFAs, although during hydrogenation of polyunsaturated fatty acids (PUFAs), small amounts of other TFAs are produced, including: *trans*-9,*cis*-12 C18:2; *cis*-9,*trans*-12 C18:2; *cis*-9,*cis*-12,*trans*-15 C18:3; and *cis*-5,*cis*-8,*cis*-11, *cis*-14,*trans*-17 C20:5 (Filip et al., 2010). TFAs have an adverse impact on cholesterol metabolism as they raise LDL-cholesterol and reduce HDL-cholesterol level, and increase the ratio of total cholesterol to HDL-cholesterol and triglyceride levels in the body (EFSA, 2010). These FAs are usually associated with an increased risk for the development of cardiovascular disease. Since health organizations have recommended reducing TFA intake to the lowest possible level, the presence of industrial TFAs in final products not higher than 2/100 g of fat (EFSA, 2010). However, while industrially produced TFAs are well known for their negative effects on human health, some researchers have proposed that ruminant TFAs have dissimilar effects on cardiovascular disease risk factors (Vučić et al., 2015). In this study, the determined TFA were vaccenic acid (*trans*-11 C18:1) and already described CLA. *Trans*-vaccenic acid makes up about 30-50% of total TFAs in milk fat (FAO, 2013). The share of analysed TFA was around 3% of total FAs with no significant difference among milk and dairy products. When considering the share of total TFAs per gram of fat, values of 0.11%, 0.49% and 1.56% for milk,

cheese and *kajmak*, respectively, are not higher than the recommended 2%. Milk and dairy products represent a significant contribution of cholesterol intake, since these products are consumed daily. The cholesterol content in cheese is mainly related to cow milk composition. The average content of cholesterol in cheese and *kajmak* (48.97 and 179.31 mg/100 g, respectively), are in accordance with those found in the literature for several low-fat cheese varieties.

Modern diets are characterized by an excessive intake of fat, especially SFAs and by the disbalance of increased n-6 PUFA to n-3 PUFA intake. The PUFA/SFA ratio is the most common parameter used to evaluate the nutritional quality of fat and potential effects on consumer health (Trbovic et al., 2017). In order to meet the health recommendations or reduce the risk of developing cardiovascular and other chronic diseases, the PUFA/SFA ratio should be greater than 0.4 (EFSA, 2010). To assess the impact on human health, the literature also suggests determination of indices that take the functional properties of FAs into account, such as AI, TI and H/H. AI refers to the relationship between the sum of the main saturates and the main non-saturates FAs, the former being considered pro-atherogenic and the latter being considered anti-atherogenic (Ulbricht and Southgate, 1991), while TI represents the relationship between pro-thrombogenic (saturated) and anti-thrombogenic (unsaturated) FAs, showing a tendency towards blood vessel clotting. H/H is the ratio between FAs which are hypocholesterolemic and hypercholesterolemic, and take into account the known effects of certain FAs on cholesterol metabolism (Lecerf, 2009). The recommended values of PUFA/SFA (higher than 0.4) as also of AI, TI (lower than 1) and H/H (as higher as possible) were not obtained in this study in any type of the product. However, in some

studies (Paszczyk et al., 2019), cow milk had the highest values of AI (3.31 ± 0.21) and TI (3.59 ± 0.19), higher than obtained in this study.

In comparison to similar studies carried out in Serbia, the results presented here showed that there are differences although small, attributable to nutritive characteristics of dairy products originating from Zlatibor. The observed variations in the nutritional content could be attributed to numerous factors including milk composition, seasonal variations, and local conditions and practices (Barać et al., 2018).

Estimation of dietary intake

Recent recommendations for healthy eating advise a daily dietary intake of milk and dairy products of 2 servings for children 2-3 years old; 2.5 servings for children 4-8 years old and 3 servings for children older than 9 years and adults, including pregnant and lactating women. One serving is equivalent to 1 cup of milk or yoghurt and 42-56 g of cheese (US Department of Health and Human Services, 2020). Meeting recommendations for dairy intake should reduce the risk of type 2 diabetes and is associated with lower blood pressure and a reduced risk of cardiovascular disease (Rice et al., 2013). Cheese and *kajmak* are among the traditional Serbian specialties that represent a significant part of the diet of the Serbian population. It is estimated that more than 30% of the daily intake of all nutrients comes from traditionally prepared meals.

Since they give a high contribution to the intake of total fats (up to 49%), it is evident that they can be associated with nutritional risk factors for the development of cardiovascular disease, which are the most common causes of morbidity and mortality in Serbia (IPHS, 2018). Due to the high share of saturated FAs, the dietary intake of 100 g of cheese or *kajmak* should contribute to the more

* Statistically significant difference within columns ($P < 0.05$)

TFA - *trans*-fatty acids; SFA – saturated fatty acids; PUFA – polyunsaturated fatty acids; AI - atherogenic index; TI - thrombogenic index; H/H - ratio of hypocholesterolaemic to hypercholesterolaemic fatty acids

Results are expressed as mean value \pm SD of five samples taken in three sampling sessions; each sample on TAG was analysed in duplicate

than half or even double, respectively, of the recommended intake of 20 g per day of saturated FAs. Similarly, the intake of cholesterol from the tested products was in a range of 16.23 to 59.77% of the recommendations (Table 5).

Regarding mineral content, milk and dairy products are important sources of calcium, magnesium, selenium and zinc (Gaucheron, 2011). Selenium and zinc are especially valuable due to their well-documented antioxidative effects (Khan et al., 2019). To determine the nutritional value of cheese or *kajmak*, fulfilments of the daily needs of various populations were estimated by comparison with the recommendations expressed as dietary reference intakes (DRI) (Institute of Medicine, 2011). In the present study, the fulfilment of recommendation was recorded in descending order as follows: sodium > calcium > chromium > zinc > selenium. The obtained data revealed that the sodium content in 100 g cheese either fulfil or exceeded the daily needs of all populations. For most population groups, fulfilment of daily needs through

cheese was 99.4% DRI and excess of recommendations was in the range of 114.74-149.16% DRI. The significantly higher fulfilments were obtained for children ($P < 0.05$) and males and females older than 50 years ($P < 0.05$) in comparison with other population groups. Salt intake with cheese and *kajmak* was in the range of 42.8-70.13%. This should be of concern since sodium (in the form of salt) is widespread in food and due to the negative health effects of high salt intake (*i.e.*, increased blood pressure, heart and kidney damage, increased incidence of certain types of cancer, etc.), and the World Health Organization recommends the daily salt intake should not exceed 5 grams (WHO, 2012), while the European recommendations are set at 6 g/day (EC, 2011).

According to results of this study, cheese in child's diet could ensure fulfilment of 47.22-67.46% of requirements for calcium, 54.22-90.37% DRI for zinc, 62.88-84.92% DRI for chromium and 47.25-70.88% DRI for selenium. Due to the lower content of

minerals, fulfilment of recommendations from *kajmak* consumption is less than from cheese, with significantly lower values for the fulfilment of the requirement for iron among females older than 18 years in comparison with males ($P<0.05$). The presence of protein, calcium and vitamin D in dairy products make them important in the normal growth and development of children, and supplementing the usual diet with dairy products significantly increases bone mineral density during childhood and adolescence (de Lamas et al., 2019). In addition to numerous positive health effects of milk and dairy consumption in childhood, several plausible mechanisms underlying the effect of dairy products on childhood adiposity have been discussed over the last decade. However, a recent review confirmed there is little evidence to support this concern (Dougkas et al., 2019).

For the adult population, 100 g of cheese should fulfil just under half the daily need for calcium for both genders, with exception of females older than 51 years and very young pregnant and lactating females which have higher calcium requirements (*i.e.*, 1300 mg *vs* 1 000 mg) and consequently the share of fulfilment of daily needs is lower (about 40%). Evidence has confirmed that the consumption of three or more dairy servings per day has beneficial effects on bone in adults, but even four servings per day may be necessary to achieve the nutrient status associated with optimal bone health in adulthood (US Department of Health and Human Services, 2020). Consuming 100 grams of cheese could ensure 26.69-46.71% DRI for chromium, while lactating women have a significantly higher needs for this mineral and therefore fulfil a smaller portion of the recommendations (20.85-22.59%). Pregnant and lactating women also have higher requirements for selenium, and fulfil only 20.25-23.63% DRI, which is

less than for the adult population (25.77-35.44% DRI). Regarding fulfilment of the need for iron, pregnant and lactating women are also in danger since their requirements are significantly higher (27 mg/day) compared to non-pregnant women (18 mg/day) or males (8 mg/day). For this population, fulfilment of the requirements is only in the range of 1.13-3.82% DRI, with significantly lower values for females older than 18 years in comparison with males ($P<0.05$). During pregnancy and lactation, the diet should provide sufficient energy and nutrients not just to ensure adequate growth and development of the foetus but also to meet mother's dietary requirements and provide good nutritional status of the mother in postpartum period and later in life. A recent review has confirmed a trend that maternal milk and dairy intake during pregnancy is positively associated with infant birth weight and length (Achón et al., 2019).

Average daily consumption of cheese and *kajmak* in the representative sample of the Serbian adult population were 27 and 21 grams per day, respectively (Statistical Office of the Republic of Serbia, 2020). With this amount of consumed cheese, adults should fulfil: 26.85-33.56% DRI for sodium; 9.81-12.75% DRI for calcium; 7.21-12.61% DRI for chromium, 6.65-9.15% DRI for zinc and 6.96-9.57% DRI for selenium. With an average consumption of 21 g of *kajmak*; the fulfilments of dietary recommendations were highest for sodium (12.26-15.33% DRI) and lowest for selenium (0.72-0.99% DRI) (*data not shown*).

Conclusions

The production of traditional and/or regional dairy products is based on natural raw materials of good quality originating from domestic animal breeds. In this sense, raw milk produced in the Zlatibor region is whole milk

and a quality raw material for the further production of dairy products. Though the recommended values for lipid quality indices were exceeded in the analysed products due to the undesirable high level of sodium, cheese and *kajmak* from Zlatibor region are still considered valuable sources of CLA, calcium, chromium, zinc and selenium. This could be attributed to several factors including animal breed, age and health, period of lactation, feeding and farming system, seasonal variations, geographical position and production process. Taking the daily consumption habits into account, a significant contribution to the quality of the diet of various populations with these products could be achieved. The data obtained in this study could be used as a case report for dairy research, and would provide information to dairy producers for product standardization and further improvements of their production system. Therefore, additional efforts are required to initiate the procedure of protection of designation of origin, which will give these products added value and enhance their valorisation.

Karakterizacija i nutritivna ocjena tradicionalnih mliječnih proizvoda s područja Zlatibora u Republici Srbiji

Dr. sc. Dragan MILIĆEVIĆ, znanstveni savjetnik; dr. sc. Danijela VRANIĆ, viša znanstvena suradnica, dr. sc. Saša JANKOVIĆ, viši znanstveni suradnik, Institut za higijenu i tehnologiju mesa, Beograd, Srbija; dr. sc. Greta KREŠIĆ, redovita profesorica, Fakultet za ugostiteljstvo i turizam Sveučilišta u Rijeci, Opatija, Hrvatska; Tina LEŠIĆ, mag. ing., viša stručna suradnica, doktorandica, dr. sc. Jelka PLEADIN, znanstvena savjetnica u trajnom zvanju, redovita profesorica, Hrvatski veterinarski institut, Zagreb, Hrvatska; dr. sc. Jelena NEDELJKOVIĆ-TRAILOVIĆ, redovita profesorica, Veterinarski fakultet, Univerzitet u Beogradu, Beograd, Srbija

Cilj ovog istraživanja bio je ustvrditi nutritivna svojstva sirovog mlijeka, sira i kajmaka proizvedenih po tradicionalnim recepturama podrijetlom s područja Zlatibora u Republici Srbiji. U tu su svrhu nakon tri uzorkovanja u razdoblju od lipnja do rujna 2019. ispitivani: kemijski sastav, minerali, profil masnih kiselina (MK), indeksi kvalitete lipida, prehrambeni unos zasićenih masnih kiselina (ZMK), kolesterola, soli i natrija. Sirovo mlijeko, sir i kajmak su se značajno razlikovali ($P < 0,05$) po svim kemijskim svojstvima, osim u udjelu laktoze, soli i ukupnih bjelančevina. U istraživanju profila masnih kiselina, najveći udio ustvrđen je za palmitinsku (C16:0), oleinsku (C18:1 cis-9) i miristinsku (C14:0) kiselinu, bez značajnih

razlika ($P > 0,05$) među proizvodima. Među MK ustvrđena je konjugirana linolna kiselina (KLK), sa srednjim vrijednostima ukupnih MK u rasponu od 0,16 % u sirovom mlijeku i kajmaku do 0,31 % u siru. U analiziranim proizvodima za indekse kvalitete lipida nisu određene preporučene vrijednosti. Unatoč visokom udjelu natrija, analizirani mliječni proizvodi mogu se smatrati dragocjenim izvorima kalcija, kroma, cinka i selen. Potreban je nastavak budućih istraživanja modifikacije ovih proizvoda s ciljem optimizacije njihove hranjive vrijednosti i zaštite oznakom izvornosti.

Ključne riječi: sirovo mlijeko, sir i kajmak, hranjiva vrijednost, tradicionalna receptura, područje Zlatibora
